Abstract

Background: Dentin hypersensitivity is characterized by short, sharp pain arising from exposed dentin in response to stimuli, typically thermal, evaporative, tactile, osmotic, or chemical, and which cannot be ascribed to any other form of dental defect or disease. Traditionally, the term dentine hypersensitivity was used to describe this distinct clinical condition; however,

several authors have also used the terms cervical dentine sensitivity (CDS) or cervical dentine hypersensitivity (CDH) or dentine sensitivity (DS), and root dentine sensitivity (RDS)/root dentine hypersensitivity (RDH). Several studies showed that casein phosphopeptide- amorphous calcium phosphate (cpp- acp) and arginine are effective in occluding dentinal tubules but information regarding dentinal tubule

Abstract:

Introduction: Intracoronaral bleaching of endodontically treated teeth has gained prominence in esthetic dentistry. Different access cavity designs and bleaching agents can influence the efficacy of the bleaching process. This in vitro study aimed to compare the effects of various access cavity designs on intracoronaral bleaching using hydrogen peroxide and carbamide peroxide.

Materials and Methods: Thirty extracted human maxillary central incisors were categorized into three groups: Group I (Traditional access cavity), Group II (Conservative access cavity), and Group III (Modified access cavity). Each group was further divided into Subgroup A (Hydrogen Peroxide) and Subgroup B (Carbamide Peroxide). After access and obturation, the bleaching agents were applied and color changes were measured using the CIE Lab color space at baseline, post-bleaching, and a two-week follow-up. ΔE values were calculated and subjected to statistical analysis.

Results: Group III (Modified access cavity) exhibited significantly higher mean color change (ΔE) than Group I (Traditional access cavity) and Group II (Conservative access cavity) for both bleaching agents ($p < 0.05$). Moreover, Subgroup A (Hydrogen Peroxide) induced greater color change than Subgroup B (Carbamide Peroxide) across all access cavity designs

Evaluate the tubule occluding ability of four desensitizing agents amine fluoride, calcium sodium phospho silicate, pro-arginin and CPP-ACP (casein phosphopeptide-amorphous calcium phosphate) using scanning electron microscope.
